Economic burden of asthma in Singapore

Eric A Finkelstein,1 Eden Lau,1 Brett Doble,1 Bennett Ong,2 Mariko Siyue Koh3,4

ABSTRACT

Background and objective Up-to-date economic burden of asthma in Singapore is currently unknown.

Methods We quantify the per capita and total annual costs of asthma for adults and children by level of symptom control (uncontrolled, partly controlled, and well controlled) via a cross-sectional online survey administered to a national web panel. Participants were asked about healthcare utilisation, days missed from work, and reduced productivity due to their symptoms. These values were then monetised and multiplied by prevalence estimates of adult and child asthmatics to generate total costs.

Results A total of 300 adults and 221 parents of children with asthma were included in analysis. The total annual cost of adult asthma was estimated to be SGD 1.74 billion (US$1.25 billion) with 42% coming from the uncontrolled group, 45% from the partly controlled group, and 13% from the well-controlled group. For children, the total cost is SGD 0.35 billion (US$0.25 billion), with 64%, 26% and 10% coming from each group respectively. Combined, the annual economic burden of asthma in Singapore is SGD 2.09 billion (US$1.50 billion) with 79% due to productivity losses.

Conclusion Poorly controlled asthma imposes a significant economic burden. Therefore, better control of disease has the potential to generate not only health improvements, but also medical expenditure savings and productivity gains.

INTRODUCTION

Asthma is a major chronic respiratory disease characterised by inflammation and constriction of the air passages.12 It manifests through recurrent attacks of symptoms, including shortness of breath, wheeze, chest tightness and cough.3 4 It affects approximately 300 million people globally and ranks 16th as the leading cause of years lived with disability.4 5

Inhaled corticosteroids (ICS) are the most effective treatments and standard of care for asthma.4 6–8 ICS reduces asthma mortality and exacerbations while improving lung function and symptom control. In the Asia-Pacific region, despite the proven efficacy of ICS medications,9–12 most patients continue to rely on reliever medications to treat acute symptoms, resulting in suboptimal control.4

More than 40% of patients report at least one unscheduled emergency department (ED) visit or hospitalisation annually as a result of an asthma attack.2 13 Poorly managed asthma also generates avoidable direct costs through physician visits, diagnostic tests, medications and hospitalisations and greater indirect costs in the form of increased work absenteeism and presenteeism (ie, reduced productivity while at work), and in the case of a child asthmatic, time off for parents to care for sick children.14 15

The direct and indirect burden due to asthma is available for numerous countries but no up to date information is available for Singapore.13–22 The most recent Singapore-based study is over two decades old and is likely no longer relevant due to changes in care pathways, costs of health services, and wage rates.23 We therefore quantify the direct and indirect costs of asthma for adults and children by level of symptom control (uncontrolled, partly controlled, and well controlled). The results will help employers, providers and policy-makers understand the burden imposed by asthma for adults and children by level of symptom control.

METHODS

A cross-sectional online survey was administered to English to Singapore residents who are members of a national web panel. Participants were recruited through email invitations in early 2020 and provided with a link to a screener. Eligibility, as shown in online supplemental appendix A, required being a Singaporean citizen or permanent resident over age 21, a previous diagnosis of asthma...
or experiencing two or more of the following symptoms not otherwise explained: wheezing, shortness of breath, cough or tightness in the chest with worsening symptoms at night and/or in the morning or that vary over time or in intensity. These criteria were adapted from the National Asthma Education and Prevention Program diagnostic guidelines in consultation with clinical experts.24

The screener identified 315 adult asthmatics (aged 21–65) and additionally, 257 adults who are parents of at least one child (aged 4–20 years) with asthma who consented to participate. Those who completed the questionnaire were compensated by the vendor.

All respondents reported demographic information and monthly employment income (online supplemental appendix A). Participants also responded to Section A of the Global Initiative for Asthma (GINA) questionnaire,8 a validated four-question instrument to measure degree of symptom control: frequency of symptoms, reliever use and inhibition in daily activities. Scoring of symptom control was done according to GINA recommendations: well controlled if responses to all questions were ‘No’, partly controlled if one to two responses were ‘Yes’, and uncontrolled if three to four responses were ‘Yes’.8

To quantify healthcare utilisation, participants were asked about frequency of healthcare use ‘due to your symptoms’ over the prior 12 months as shown in online supplemental appendix A. Checklists were provided which inquired about frequency of physician and outpatient visits, medications, diagnostic tests, ED visits and hospitalisations. To monetise utilisation, unit costs were applied to each type of service based on costs collected through publicly available sources (online supplemental appendix tables C1 and C2). Only those in the labour force were able to generate costs for absenteeism and presenteeism. All costs are reported in 2020 Singapore dollars accompanied by the equivalent in US dollars (SGD = US$0.72).

Lost productivity was quantified using a modified version of the Workplace Productivity and Activity Impairment Questionnaire: Specific Health Problem v2.25 Given the episodic nature of asthma, the investigators found it more appropriate to apply a recall period of 1 month instead of the instrument’s original period of 1 week. Absenteeism was captured by having respondents indicate the number of hours missed from work due to problems associated with asthma in the past month. This figure was then multiplied by 11.5 to generate annual hours missed and monetised by multiplying by an hourly wage for each respondent. For full-time employees (160+monthly hours), hourly wages were calculated by dividing reported monthly income by the sum of reported number of monthly hours worked and hours missed from work. Monthly income was assumed to be the midpoint of the reported income category or SGD 10 500 for those who report earnings in the SGD 10 000 or more category. For part-time employees or full-time employees with missing income data, hourly wages were estimated based on the mean hourly wage for full-time employees in the corresponding occupation category. If a mean hourly wage for full-time employees was not available for a category, missing income was estimated based on the mean hourly wage for full-time employees in the entire sample.

Presenteeism was captured by participants indicating the degree to which asthma symptoms affect their productivity while working on a scale of 0–10, with 0 being ‘no symptoms and/or symptoms had no effect on my work’ and 10 being ‘symptoms completely prevented me from working’. Monthly presenteeism hours were calculated as the product of a participants’ presenteeism scale response and their reported monthly number of hours worked.25 This estimate was then annualised and monetised using an analogous approach as for absenteeism.

Surveys for parents answering on behalf of their child were similar except questions were framed with ‘due to your child’s asthma’. If a participant indicated more than one child with asthma, they were asked to consider only the oldest child. Aside from this framing, the questions were analogous to the adult survey, except for absenteeism which was captured using the Caregiver Indirect and Informal Care Cost Assessment Questionnaire.26 Absenteeism costs were conservatively set to zero for respondents not in the labour force.

Once the data were available, logic checks were conducted to ensure the reported data were in plausible ranges and to identify any responses that seemed problematic. The resulting dataset allowed for quantifying the per capita direct healthcare costs and indirect costs for absenteeism and presenteeism separately for adults and children. These were then stratified by levels of symptom control (well controlled, partly controlled, and uncontrolled) to generate averaged per capita costs for each stratum, which could then be multiplied by the number of individuals within each stratum to generate total costs by strata. The latter figure required us to know how many adults and children in Singapore currently suffer from asthma stratified by symptom control. This could be estimated by multiplying population counts for adults and children times the prevalence rate for asthma for each subgroup of interest. For healthcare costs, we applied population counts for all adults and children but for costs of lost productivity we considered only counts for employed adults.

The numbers of adults and children were available from the Singapore Department of Statistics27 and the employment rate was available from the Ministry of Manpower.28 Asthma prevalence rates were not readily available. For adults and children, we applied prevalence rates of 5.1% and 8.9%, respectively, based on two studies from 2004 as more recent prevalence data was not available.29 30 Moreover, the prevalence estimates do not contain information on level of symptom control. Therefore, we estimated the prevalence rate within each symptom control category by assuming the distribution across the three categories is the same in Singapore as it is among respondents to our survey.
Patient and public involvement
The public was involved in the research only during the data collection stage, through invitations to take an online survey. They were not involved in any other parts of the research.

RESULTS
After removing suspect responses (see online supplemental appendix B), 300 adults and 221 parents of children were included in analysis. Out of the adults, 24% were uncontrolled, 38% were partly controlled, and 38% were well controlled. For children, 45% were uncontrolled, 30% partly controlled and 25% well controlled. Using these relative values and ensuring that the sum of the three categories adds to the population prevalence of 5.1% for adults and 8.9% for children yields asthma prevalence of 1.2%, 1.9% and 1.9% for uncontrolled, partly controlled, and well controlled for adults and 4.0%, 2.7%, and 2.3%, respectively, for children.

Sample characteristics stratified by control status are reported in table 1. Adult participants were on average, 36 years old, of Chinese descent (80%), married (60%), and had completed at least tertiary education (58%). Parents were on average, 39 years old, predominantly Chinese (78%), and had completed at least tertiary education (65%).

Per capita costs are presented in table 2 and online supplemental appendix table D. The left panel reveals that per capita healthcare expenditures for adults are SGD 3150 (US$2270), SGD 1010 (US$730) and SGD 270 (US$190) for the uncontrolled, partly controlled and well-controlled groups, respectively. As shown in online supplemental appendix table D, the largest contributor to healthcare costs are medications.

†Sample characteristics are representative of the parents who responded on behalf of their children.
‡This includes junior college, the Singapore–Cambridge General Certificate of Education Advanced Level (A-Level) examination, polytechnic education, diplomas, vocational training, and Institute of Technical Education (ITE) education. The A-Level is a national examination held annually in Singapore. The examination is taken by school candidates on the completion of preuniversity education at junior colleges, centralised institutions, and Integrated Programmes, and is also open to private candidates. ITE is a public vocational education institution agency in Singapore that provides pre-employment training to secondary school graduates, and continuing education and training to working adults.
The average number of asthma-related days missed from work per year for employed adults was 19 days, 10 days and 2 days, respectively (online supplemental appendix table E.1). Monetised this translates to SGD 4870 (US$3510), SGD 2400 (US$1730) and SGD 340 (US$310). Presenteeism estimates were much higher. The mean presenteeism score reported was 6, 4 and 2, which translates to annual work loss valued at 62 days, 59 days and 21 days (online supplemental appendix table E.1). Note that although the presenteeism score for the partly controlled group is one-third lower than for the uncontrolled group, annual work loss is only slightly lower because nearly twice as many in the former group work full time (35% vs 18%), thus generating much greater work loss even for the same presenteeism score. Monetised the work loss converts to losses of SGD 17 610 (US$12 720) and SGD 5230 (US$3770), for those who are either fully or partly employed, with 46% coming from those with uncontrolled asthma, 45% from the partly controlled group and 13% from the well-controlled group.

The right panel of table 2 shows per capita costs for children. Trends are similar; children with uncontrolled asthma generate the highest healthcare and absenteeism costs and children with well-controlled asthma generating the lowest costs. Healthcare expenditures make up the vast majority of costs for children. Additional details are included in online supplemental appendix table D.

Adult residents in Singapore total 3 193 502 and child residents total 627 993. The percentage of adults or parents employed either full or part time is 69%. Multiplying these counts times the asthma prevalence estimates times the per capita total costs yields total costs among adult asthmatics of SGD 0.73 billion (US$0.53 billion), SGD 0.78 billion (US$0.56 billion) and SGD 0.23 billion (US$0.17 billion) for the uncontrolled, partly controlled and well-controlled asthma groups (table 3). Aggregating across the three groups results in a total cost of adult asthma of SGD 1.74 billion (US$1.25 billion) with 42% coming from the uncontrolled group, 45% from the partly controlled group and 13% from the well-controlled group.

For children, total costs are SGD 0.22 billion (US$0.16 billion), SGD 0.09 billion (US$0.06 billion) and SGD 0.03 billion (US$0.02 billion), respectively (table 3). Summing across groups yields a total cost of SGD 0.35 billion (US$0.25 billion) for child asthma, with 64% coming from those with uncontrolled asthma, 26% from partly controlled and 10% from the well-controlled group. Aggregating costs for adults and children reveals that the total annual economic burden of asthma in Singapore is SGD 2.09 billion (US$1.50 billion), with 46% coming from those with uncontrolled asthma, and

only 13% from those with well-controlled asthma. Children are responsible for 17% of the total.

DISCUSSION
This study quantified the economic burden of asthma in Singapore by level of symptom control. These costs are substantial, totaling SGD 2.09 billion (US$1.50 billion) annually, with 79% of coming from lost productivity. These costs mainly come from presenteeism, as results reveal that those with asthma tend to come to work but perform below their potential due to their symptoms. Moreover, although they represent only 29% of the total asthma group, the uncontrolled group is responsible for 46% of total costs, whereas the 35% of the asthma population that is well controlled represent only 13% of the total. As a result, if all those with suboptimal control could be improved to well-controlled without cost, the total cost of asthma would be reduced by SGD 1.35 billion (US$0.97 billion). Although greater control would come at a cost, many of the asthma control interventions, including national asthma programmes, ICS medications, newer biological treatments, and bronchial thermoplasty, have been shown to be cost-effective. Our results further show the potential for cost savings given the high medical cost and productivity burden among those with poor control.

Our results are in line with prior estimates. We find that 87% of our sample has uncontrolled or partly controlled asthma, which is identical to that reported in a prior study in Singapore. We estimate annual asthma per capita healthcare costs across all symptom groups at SGD 1290 (US$930). Consistent with Singapore being a low-income country, health expenditures on asthma are comparatively low compared with other locations, especially in the US.

In Singapore, Malay asthmatics have higher healthcare costs than Chinese and5 for asthma.54 For asthma-related absenteeism, our sample reports an average of 6.6 hours missed over the past month, which is roughly half of the 13.6 hours average reported in a study of six countries. Our respondents also report an average score of 4 on the presenteeism scale, just one unit above the average score from the same international study (4 vs 3). This study is not without limitations. A primary limitation is the potential for selection bias of the survey respondents. The survey relies on a convenience sample of asthma participants (and their parents) from an online panel and there is no way to determine whether those who chose to participate are representative of individuals with asthma in the broader community. Because the survey relies on self-report, it is also prone to recall and self- and parent-report bias. Also, although we were able to quantify per capita and total medical costs, we did not assess whether these costs are paid by government, private insurance, out of pocket or other sources. Future studies should validate these results with utilisation or claims data from other sources and identify the percentage of costs that are funded by various payers.

Because we do not have asthma prevalence data by race or socioeconomic status, we also assume there are no differences by these factors in the use of health services. Yet, in Singapore, Malay asthmatics have higher healthcare utilisation and greater work impairment. They are also under-represented in the online panel, suggesting an additional source of potential bias. The analysis is also limited by use of dated statistics and imputation to generate current asthma prevalence by level of symptom control, by excluding those below age 4 and over age 65, and by not including caregiver costs for those who may take care of adult asthmatics. For all of these reasons, our prevalence, unit cost and total cost estimates are potentially biased and associated with high variability that could not be properly estimated. Rather than attempt to incorporate this uncertainty into the analysis, we note that even if our figures are off by an order of magnitude, more precise estimates will not change the conclusion that asthma imposes a significant economic burden in Singapore and that the potential exists to reduce the burden through effective policies and treatments.

Contributors EAF supervised this study overall. He conceptualised the study and methodology, conducted formal analyses, validated the survey, drafted the original version of the manuscript and was involved in all manuscript revisions leading to submission. EL conducted formal analyses, drafted the original version of the manuscript and was involved in all manuscript revisions leading to submission. BD conceptualised the study and methodology, validated the survey, worked on writing and editing the manuscript. BO acquired funding for this study, conceptualised the study and methodology, validated the survey, and was involved in all manuscript revisions leading to submission. MSK conceptualised the study and methodology, validated the survey, and was involved in all manuscript revisions leading to submission.

Funding Funding for the study was provided by AstraZeneca Pte. Ltd., Singapore.

Competing interests EAF: has done paid consulting work for AstraZeneca and other Pharma companies. BO: is an employee of AstraZeneca. However, he had no role in the analysis and AstraZeneca did not have a right of refusal on publication. MSK: has grant support from Astra-Zeneca, and received honoraria for lectures and advisory board meetings paid to her hospital (Singapore General Hospital) from GlaxoSmithKline, Astra-Zeneca, Sanofi, Novartis and Boehringer Ingelheim, outside the submitted work.

Patient consent for publication Not required.

Ethics approval Institutional Review Board (IRB) approval was obtained (NUS-IRB Ref: S19-289).
